BE IT KNOWN that I, ***Maria Cristina MORET CODINA***, have
invented certain new and useful improvements in

***UNIT FOR CONNECTING CONDUCTORS
TO TERMINALS***

of which the following is a complete specification:

BACKGROUND OF THE INVENTION

The present invention relates to a unit for connecting conductors to terminals.

More particularly, the present invention relates to a unit for terminals which constitute the central internal body of the electric devices known and currently used, such as switches, pushbuttons, mounting plates and the like, a unit which is designed to allow connecting the external conductors which have side access, quickly and with full effectiveness and guaranty.

One of the tasks which presently requires special care and therefore have repercussions on the times for mounting the installations, is connecting the terminals of conductors which has a repercussion on the electric device, and operation which requires, either an installation prior to the terminals, or an industrious hand folding or braiding around the setscrew itself on the terminal.

SUMMARY OF THE INVENTION

Accordingly, it is an object of present invention to provide a unit for quick connection to terminals which avoids the drawbacks of the prior art.

5 These drawbacks are overcome by using the unit for terminals which is provided with a mechanical device by means of which immediate fastening and setting is carried out and without any prior preparation of the clean end of the cable, a conductor which have to be located within the receptacle of the connecting terminal, the said cable having a side access with respect to the unit longitudinal plane of symmetry which is disclosed below.

10 This device will also allow to provide that in a single unit several devices of quick connection are arranged allowing for connecting two conductors, and it is provided that connecting or disconnecting one of the conductors will absolutely not affect the other, that is to say, that first one can be connected and thereafter the other without disconnecting the first is required, offering identical possibility in the reverse operation of disconnection.

In keeping with these objects and with others which will become apparent hereinafter, one feature of present invention resides, briefly stated in a body; at least two mechanical devices each formed and operative for a quick connection of one conductor to each terminal and for disconnection of said one conductor from each terminal, said mechanical devices being formed so that each of said mechanical devices provides a quick connection of one of the conductors to each of the terminal, and a disconnection of said one conductor from each terminal without impairing the other of the mechanical devices and thereby the other conductor.

The novel features which are considered as characteristic for the present invention are set forth in particular in the appended claims. The invention itself, however, both as to its construction and its method of operation, together with additional objects and advantages thereof, will be best understood from the following description of specific embodiments when read in connection with the accompanying drawings.

BRIEF DESCRIPTION OF THE DRAWINGS

Figure 1 is a front view of the unit, partly sectioned, in order to show the location of one of its elements of quick connection;

5 Figure 2 is an also front view of the block, identical to that of the preceding figure, with two symmetrical areas partly sectioned, also showing the arrangement of the quick connecting elements and, namely, the different position of two contiguous driving levers;

10 Figure 3 is a side sectional view, through plane AA, of Figure 1, showing the arrangement of the different mechanisms of connection, as well as the mounting plate on which the unit of terminals is installed;

Figure 4 is a detail at larger scale of the lower part of the driving lever of the mechanism; and

15 Figure 5 is a part sectional view of the unit corresponding to Figure 3, showing the end positions of the driving lever, together with the elastic metal strips with which the mechanism is provided, and the fastening of the cable in the connection area.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

A unit of terminals with quick connection in accordance with the present invention has a prismatic body 1, hollow inside, provided with side ribs or flanges 2 for fastening it at the corresponding places of the electric device, not shown, as well as the top side ribs 3, also by fastening. All the lower part of the block is closed by the mounting plate 4.

The central part of the body has a series of walls which constitute, first, the housing 5 where the driving lever of the quick connection mechanism is located. These small walls are extending within the body 1, constituting the spaces 6 designed to the suitable location of the corresponding elements, not drawn, of the electric device to which the terminal unit will be jointed.

At the external part of the body 1 and at the corresponding area of the lower part of the housings 5 there are holes 7 which provide access by the sides the ends 8 of the conductors to be connected. These holes 7 also affect the coinciding top edge of the closing base plate 4.

The quick connection mechanism is constituted by a driving lever 9 generally formed by two identical and independent levers 9a and 9b, figures 1 and 2 symmetric with respect to their plane of contact.

Each lever possesses a flat top base 10 by which they can be driven, by pushing it down and which is ending at its lower part in a rounded shape 11a, together with a stop latch 11b. The rounded end 11a will remain supported on the respective elastic metal strip 12 which keeps the lever up with the stop latch 11b retained against the lower edge 13 of the housing small wall 5, as it is noted in the detail of Figure 4.

Sub 12 The elastic metal strip 12 remains supported on the bottom of the plate 4, while its top end, divided into two symmetric and spaced parts goes between the contact bases 14 having a corrugated shape of a convex bar, located facing the holes of the side inlets 7 for the conductors to be connected 8. These contact bases 14 are downwardly extended 14a ending on the bottom plate 4, keeping the connection through the metal element 15 located for that purpose, with the contacts the electric device 16 possesses, as illustrated in Figure 3.

Sub
A37

The quick connection mechanism is arranged so that each device having available symmetric levers 9a and 9b will allow the location and connection of two conductors 8. Under the levers there are also located two divided top parts of the elastic metal strip 12 symmetrically and independently arranged, as well as the two contact bases 14 also symmetrically and independently arranged as it is shown in details in Figures 1 and 2. In the second figure, one of the two symmetric levers 9a is drawn located lower, a position that it will adopt when conveniently pressed down.

At the moment when the lever 9 is pressed down position 9a, it bends downwards corresponding elastic metal strip 12, which remains at the position 12a figure 5, under the contact base 14, which will allow that the end of the conductor 8 can be quite easily introduced through related side hole 7, being situated under the convex bar of the contact base 14. When the lever, at that moment, is no more pressed down, it leaves its position 9a, passing to the normal position 9 pushed by the elastic metal strip 12 which, in turn, strongly presses the conductor 8 against the contact base 14. The quick connection of the conductor 8 is thus carried out, with full guaranty, within the body 1, through the side access Figure 5 clearly shows this action of the device of the invention.

As it has been stated before, this connection is carried out without absolutely impairing the positioning of the second conductor 8a previously connected, as well as disconnecting them when they are connected.

5

It is obvious that the invention does not require screws at any moment for the connection as it was usual up to now, which allows an independent action in each case.

10

Sufficiently disclosed the unit of terminals for quick connection, object of this utility model, it must be stated that any variation of sizes, shapes and external appearance, as well as any kind and quality of materials used for the embodiment of the said unit, will absolutely not impair the spirit thereof which is summarized in the following claims.
